An effective synthesis of tricyclic, nonclassical cannabinoids has been developed on the basis of a cation-ol efin cyclization that forms the two nonaromatic rings with the desired stereochemistry in a single step.

## Introduction

Earlier efforts in our groups had revealed a correl ation between the stereochemistry of the southern aliphatic hydroxyl (SAH) group, the chain length, and the affinity of the compounds for CB1 and CB2, the two known cannabinoid receptors, within a series of hybrid cannabinoids. ${ }^{1}$ A systematic study, in which C6 stereochemistry and the chain length of the group appended to this carbon were varied, revealed that the C6 $\beta$ hydroxypropyl analogue had a high affinity for both CB1 and CB2 cannabinoid receptors. To further refine our understanding of the stereochemical preferences of the receptor for the hybrid cannabinoids, we sought to obtain additional information on the stereochemical preferences of the SAH group with respect to its ability to interact with the CB1 and CB2 binding sites. This information was obtained by introducing a triple or double bond at the C2" position of the $6 \beta$-hydroxypropyl chain and led to a series of novel cannabinoid receptor probes (1-3). The challenge to the synthetic chemist that is posed by these structures is control of C6 stereochemistry. There is an insignificant difference in energy between the C6 diasteroisomers of 1; consequently, stereochemical control cannot be exercised under reaction conditions that would lead to equilibration of this stereogenic carbon. A stereoselective approach to $\mathbf{1}$ is only possible through a kinetically controlled process.

An early solution to the problem posed by C6 stereochemistry is illustrated by eq 1 . Intramolecular oxymer-curation-demercuration of 4 led to 5 in $43 \%$ yield. ${ }^{1,2}$ The probable origin for the preference for the axial acetoxymercuriomethyl group has been discussed. ${ }^{3}$ AIthough the yield for the dihydrobenzopyran ring-forming step was modest in this instance, this approach was

[^0]
successfully applied to the synthesis of cannabinoid analogues. ${ }^{1}$

A related approach from our group is shown in eq 2, wherein the cyclization of 6 leads to formation of two rings and also determines the stereochemistry at carbon atoms 10a, 6a, and 6 in a single process. ${ }^{4}$ The yield of product 7 was low, and we were unable to improve the reaction. The synthesis which is described herein evolved from a consideration of these earlier efforts.

## Discussion

Two mechanisms can be imagined which would rationalize the conversion of 6 to 7. Either an intramolecular Diels-Alder cycloaddition of an o-quinone methide ${ }^{5}$ or a cation-olefin cyclization initiated by ionization of the benzylic alcohol function. ${ }^{6}$ The intramolecular DielsAlder reaction would be expected to be concerted or synchronous, whereas the cation-olefin process would, in all likelihood, be stepwise. Cyclization of $\mathbf{6}$ may be nonconcerted, as evidenced by the isolation of a partially cyclized byproduct, and this is in part responsible for the poor yield of the reaction. ${ }^{7}$ If the yield for such a cyclization could be improved, it would represent a very attractive method; preparation of intermediates such as 6 is generally much more convenient than the synthesis of compounds analogous to 4 . Since we had evidence that the cyclization of 6 was not concerted, we postulated that unsaturation at $\mathrm{C} 2^{\prime \prime}-\mathrm{C} 3^{\prime \prime}$ would lead to a more stable carbocationic intermediate, and that this in turn would result in an improved yield for the cyclization. Our hypothesis is supported by J ohnson's approach to corticosteroids in which a strategically placed 2,2-dimethylvinyl group which stabilizes a key carbocation cyclization intermediate results in dramatically enhanced product yield, and shorter reaction time. ${ }^{8}$ There is a risk to this approach. As the cations along the reaction pathway become more stable, the reaction is likely to become less stereoselective in a cyclization in which stereochemistry is kinetically controlled, as is the case at hand. ${ }^{9}$ Notwithstanding, we decided to proceed by designing a stabilized intermediate for the key cyclization step.

The retrosynthesis of $\mathbf{1}$ leads to an aliphatic fragment 12 (Scheme 1) and to an aromatic fragment 17 (Scheme 2). Trost's elegant method was used to control the geometry of the trisubstituted alkene in the aliphatic fragment. ${ }^{10}$ Palladium acetate catalyzed coupling of propargyl alcohol with ethyl 2-butynoate led to enoate 8 as a single isomer in $75 \%$ yield. Conversion of $\mathbf{1 0}$ to allylic chloride $\mathbf{1 1}$ took place in $70 \%$ yield with NCS and triphenylphosphine. ${ }^{12}$ The allylic chloride was labile, and was immediately treated with the anion derived from acetaldehyde tertbutylimine and LDA. ${ }^{13}$ I mine hydrolysis with acetic acid in aqueous THF gave aldehyde 12 in $77 \%$ overall yield from 11.

acceptable yield of 16. Cleavage of the two phenolic methyl ether groups in $\mathbf{1 6}$ was accomplished by exposure to boron tribromide. ${ }^{17}$ Allylation with allyl bromide and tetra-n-butylammonium hydroxide in dichloromethane/ $\mathrm{H}_{2} \mathrm{O}$ led to monoallyl ether $\mathbf{1 7}$ in $81 \%$ yield for the two steps from 16. ${ }^{1}$ It was essential for the success of the allylation that electrophile be added before the base. The reverse sequence led to complicated mixtures of products. This reactivity is typical and is a consequence of the sensitivity of the phenoxide intermediate to traces of oxygen.

The two large fragments were combined in an aldol reaction (Scheme 3 ) which produced $\mathbf{1 8}$. It is critical that the aldol reaction be quenched at low temperature with acetic acid, otherwise the lithium alkoxide undergoes retro-aldol fragmentation during quench and workup. Reduction of the ketone carbonyl group of 18 with DIBALH led to recovery of $\mathbf{1 9}$ in low yield and with only

modest (ca. 3:1) selectivity for the syn diol isomer. ${ }^{18}$ The low stereoselectivity in this step is an indication of multiple, competing modes of bidentate complexation of 18 with the Lewis-acidic reagent. Reduction of $\mathbf{1 8}$ with sodium borohydride was not stereoselective, but produced 19 as a ca. 1:1 mixture of syn and anti diastereoisomers in 97\% yield. Exposure of the diastereomeric mixture of al cohols $\mathbf{1 9}$ to trifluoroacetic acid in dry chloroform at 0 ${ }^{\circ} \mathrm{C}$ produced tricyclic alcohol 20 as a ca. 1:1 mixture of C9 diastereoisomers in 76\% yield, following column chromatography. The diastereoisomers of 19 were separated by flash column chromatography, and were cyclized independently to give 20, again as a ca. 1:1 mixture of C9 diastereoisomers in each case. Oxidation of the diastereoisomers of $\mathbf{2 0}$ with the Dess-Martin periodinane gave ketone 21. ${ }^{19}$ The relative stereochemistry of the three contiguous asymmetric carbon atoms in $\mathbf{2 1}$ was determined through a series of NOE experiments on 1 (vide infra).

The ease and the high yield for the cyclization of 19 is in sharp contrast with our experience with 6. Although in the case of 6 it is concei vable that the difluoromethylene function exerted some deleterious influence on the cyclization, it appears to be more likely that the stabilization of the presumed carbocationic intermediate derived from 19 by the adjacent alkyne function was decisive in determining the success of the cyclization of 19. Cyclization of 19 produces exclusively the desired stereochemistry at C10a, C6a and C6, but is stereorandom at C9. This suggests that under the conditions for the cyclization there is an insignificant difference in transition state energies, one with the hydroxyl group equatorial, the other axial. This is consistent with the experience of others in this area. ${ }^{20}$
Ketone 21 was exposed to (methoxymethyl)triphenylphosphorane to give enol ether 22 in $88 \%$ yield as a 2:1 mixture of geometrical isomers. ${ }^{21}$ Selective hydrolysis of the enol ether function of 22, followed by epimerization of the resulting aldehyde and reduction with sodium borohydride gave $\beta$-equatorial alcohol 23 in 91\% overall yield from 22. Palladium-catalyzed reductive cleavage of the phenolic allyl ether function ${ }^{22}$ took place in $94 \%$ yield to produce phenol 24. Silyl ether removal with triethyIamine trihydrofluorideled to $\mathbf{1}$ in $96 \%$ yield. ${ }^{23}$ Reductive cleavage of the allyl ether after removal of the silyl group resulted in sharply attenuated yields of $\mathbf{1}$ (ca. 40\%), as a result of competing reduction of the alkyne function to produce 2. The bulky silyl protecting group evidently suppressed reduction of the adjacent alkyne. Semihydrogenation of $\mathbf{1}$ in the presence of Lindlar's catalyst gave $\mathbf{2}$ in 91\% yield; isomerization of an irradiated (tungsten filament lamp) solution of $\mathbf{2}$ in benzene in the presence of phenyl disulfide produced 3 in $64 \%$ yield. ${ }^{24}$

The stereochemistry of $\mathbf{1}$ was determined as follows (Figure 1). Irradiation of the C10a methine signal at 2.50 ppm resulted in strong NOE enhancements of the signals

for the C6 methyl at 1.37 ppm , and for the C9 methine at 3.29 ppm . Since the ring junction stereochemistry must be trans, because of the large ( $)=11.1 \mathrm{~Hz}$ ) coupling constant between the protons at C10a and C6a, the stereochemistry of $\mathbf{1}$ is as shown.

The affinities of the racemates of $\mathbf{1 - 3}$ for the CB1 and CB2 cannabinoid receptors were obtained using procedures described elsewhere ${ }^{1}$ and are summarized in Table 1.
All three compounds exhibit significantly high affinities for the CB1 and CB2 receptors with $\mathrm{K}_{\mathrm{i}}$ values ranging from subnanomolar to single digit nanomolar. Thus, these classical/nonclassical hybrid analogues which encompass conformationally restricted southern aliphatic chains can be considered as a novel class of highly potent synthetic cannabinoids. Additionally, the three analogues exhibit a certain degree of selectivity for the CB1 or CB2 receptors. In this regard $\mathbf{3}$ is the most interesting, with a 13 -fold selectivity for CB1 over CB2, a feature which places it among the most CB1-selective cannabinoids known to date.

## Conclusion

A concise, high-yielding procedure for assembly of hybrid cannabinoids has been described. The synthesis provides racemic materials, however, semipreparative separation of the enantiomers of $\mathbf{1 , 2}$ and $\mathbf{3}$ can be readily accomplished on a Daicel Chiralcel-OD HPLC column. Consequently, this method offers much more rapid and convenient access to materials than our earlier route. ${ }^{1}$ The synthesis of other analogues of this series will be carried out in the future according to the protocols described herein. Noteworthy features of the synthesis include the application of Trost's metallo-ene reaction for the stereospecific synthesis of aldehyde 12, and the efficient cyclization of 19, which preserves the stereochemical information present in the trisubstituted olefin. This methodology is potentially applicable to the stereospecific synthesis of other dihydrobenzopyrans.

## Experimental Section

HPLC was performed using a $5 \mu \mathrm{~m}$ Phenomenex silica column ( $150 \times 4.60 \mathrm{~mm}$ ). Purity and homogeneity of all materials was determined chromatographically and from ${ }^{1} \mathrm{H}$ NMR and ${ }^{13}$ C NMR, combustion analysis or HPLC. Tetahydrofuran and ether were purchased in anhydrous grade and
stored over activated $4 \AA$ A molecular sieves. Diisopropylamine and pyridine were distilled from calcium hydride and stored over potassium hydroxide. Nitromethane and chloroform were distilled from calcium hydride and stored over activated $4 \AA$ molecular sieves. Methylene chloride, acetic anhydride, and benzene were distilled from calcium hydride immediately before use. Methanol was distilled from $\mathrm{Mg}(\mathrm{OMe})_{2}$ and stored over activated $4 \AA$ molecular sieves. N-Chlorosuccinimide was recrystallized from benzene. Other reagents were used as received. All moisture-sensitive reactions were performed under a static nitrogen or argon atmosphere in oven-dried or flame-dried glassware. Combustion analyses were performed by Desert Analytics, Inc. Homogeneity and purity of all compounds was determined by HPLC.

Purification by flash column chromatography on silica gel ( $3 \%$ to $4 \%$ to $5 \%$ EtOH in $\mathrm{CH}_{2}-$ $\mathrm{Cl}_{2}$ ) gave alcohol 1 ( $120 \mathrm{mg}, 96 \%$ yield) as a white foam: mp $87-88^{\circ} \mathrm{C} ; \mathrm{R}_{\mathrm{f}}=0.18\left(5 \% \mathrm{EtOH}\right.$ in $\left.\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$; ${ }^{1} \mathrm{H}$ NMR $(300 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}\right) \delta 6.44(\mathrm{~d}, \mathrm{~J}=1.7 \mathrm{~Hz}, 1 \mathrm{H}), 6.24(\mathrm{~d}, \mathrm{~J}=1.7 \mathrm{~Hz}, 1 \mathrm{H})$, 5.68 ( s br, 1H), $4.37(\mathrm{~d}, \mathrm{~J}=4.6 \mathrm{~Hz}, 2 \mathrm{H}$ ), $3.59-3.45(\mathrm{~m}, 2 \mathrm{H})$, 3.29 (d br, J $=12.5 \mathrm{~Hz}, 1 \mathrm{H}), 2.50(\mathrm{td}, \mathrm{J}=11.1,2.7 \mathrm{~Hz}, 1 \mathrm{H})$, $2.20(\mathrm{~m}, 1 \mathrm{H}), 1.97-1.69(\mathrm{~m}, 5 \mathrm{H}), 1.50-1.44(\mathrm{~m}, 2 \mathrm{H}), 1.37(\mathrm{~s}$, $3 \mathrm{H}), 1.27-0.76(\mathrm{~m}, 17 \mathrm{H}), 0.84(\mathrm{t}, \mathrm{J}=6.8 \mathrm{~Hz}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\left(75 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 154.4,153.0,150.3,108.8,108.1,106.1$, 87.3, 83.1, 74.7, 68.4, 51.2, 48.2, 44.5, 40.6, 37.4, 34.3, 33.0, 31.8, 30.1, 29.5, 28.7, 28.3, 24.6, 22.7, 19.7, 14.1; IR (neat) 3340 (br), 2935, 2860, 1625, 1575, 1420, $1330 \mathrm{~cm}^{-1}$; mass spectrum $\mathrm{m} / \mathrm{z} 428$ (M+ ${ }^{+}$67), 344 (43), 249 (33), 105 (30), 91 (50), 85 (32), 83 (33), 79 (40); exact mass cal cd for $\mathrm{C}_{27} \mathrm{H}_{40} \mathrm{O}_{4} 428.2927$, found 428.2939.
(Z)-Alkene 2. To a solution of quinoline ( $31 \mathrm{mg}, 0.24 \mathrm{mmol}$ ) in 5 mL of benzene at room temperature was added Lindlar catalyst ( $27 \mathrm{mg}, 2.5 \%$ on $\mathrm{CaCO}_{3}, 6.3 \mu \mathrm{~mol}$ ) and a solution of alkyne $\mathbf{1}(35 \mathrm{mg}, 0.082 \mathrm{mmol})$ in 20 mL of benzene. The static nitrogen atmosphere was replaced by hydrogen from a double balloon and the reaction mixture was stirred at room temperature for 2 h , filtered through Celite, and concentrated.     (6) The two mechanisms are related. Participation of the nonbonding electron pair of one of the phenolic oxygen atoms in the ionization of the benzylic al cohol would produce the protonated o-quinone methide.
    (7) A reviewer has pointed out that the partially cyclized byproduct which is derived from 6 cannot be taken as evidence that the reaction which leads to $\mathbf{7}$ is nonconcerted. The partially cyclized byproduct may have been formed by a competing process.
